

# **Introduction to the Theory of Computation**

**Set 10 — Complexity (1)**

# Complexity of Algorithms

Among *decidable* problems, we still have **levels of difficulty** for algorithms

We may consider an algorithm more difficult for a variety of reasons

- Takes longer to execute
- Requires more memory to execute

**Time complexity:** Given an algorithm and an input string, how long will the algorithm take to execute?

# Example

## INSERTION-SORT(A)

1. For  $j = 2$  to  $\text{length}(A)$
2.      $\text{key} := A[j]$
3.      $i := j-1$
4.     While  $i > 0$  and  $A[i] > \text{key}$
5.          $A[i+1] := A[i]$
6.          $i := i-1$
7.      $A[i+1] := \text{key}$

# Trace

**4 6 1 8 5 3**

- Start by looking at 6 & compare to 4
- $4 \leq 6$
- Next look at 1

**1 4 6 8 5 3**

- 8 is okay
- Move 5 then move 3

**1 4 5 6 8 3**

**1 3 4 5 6 8**

## INSERTION-SORT(A)

1. For  $j = 2$  to  $\text{length}(A)$
2.      $\text{key} := A[j]$
3.      $i := j-1$
4.     While  $i > 0$  and  $A[i] > \text{key}$
5.          $A[i+1] := A[i]$
6.          $i := i-1$
7.      $A[i+1] := \text{key}$

# How long does insertion sort take?

Two loops

Outer loop executed  $(n-1)$  times

$n = \text{length}(A)$

Inner loop executed up to  $j$  times

Total time is at most  $\sum_{1 \leq k < n} (4 + \sum_{1 \leq i < k} 3)$

$$\sum_{1 \leq k < n} 4 + \sum_{1 \leq k < n} 3k$$

$$4(n-1) + 3[(n+1)n/2 - 1] =$$

$$4n - 4 + 1.5n^2 + 1.5n - 2 =$$

$$1.5n^2 + 5.5n - 6$$

INSERTION-SORT(A)

1. For  $j = 2$  to  $\text{length}(A)$
2.      $\text{key} := A[j]$
3.      $i := j-1$
4.     While  $i > 0$  and  $A[i] > \text{key}$
5.          $A[i+1] := A[i]$
6.          $i := i-1$
7.      $A[i+1] := \text{key}$

# Big-O Notation

**In general, the time complexity will be a sum of terms that is dominated by one term**

- **For example,  $n^2 + 2n - 3$  is dominated by the  $n^2$  term**

**Time complexity is most concerned with behavior for large  $n$**

- **We disregard all terms except for the dominating term**
- **$n^2 + 2n - 3 = O(n^2)$**

# Asymptotic Upper Bound

**Definition:** Let  $f$  and  $g$  be two functions from  $\mathbb{N}$  (natural numbers) to  $\mathbb{R}^+$  (positive real numbers).

Then  $f(n) = O(g(n))$  if positive integers  $c$  and  $n_0$  exist such that for every  $n \geq n_0$ ,  
 $f(n) \leq c \times g(n)$ .

In this case, we say that  $g(n)$  is an *upper bound* for  $f(n)$ .

# Example

$$3n^4 + 5n^2 - 4 = O(\quad)$$

$3n^4 + 5n^2 - 4 \leq 4n^4$  for every  $n \geq 2$  since

$$3n^4 + 5n^2 - 4 \leq 4n^4$$

$$\Rightarrow n^4 - 5n^2 + 4 \geq 0$$

$$\Rightarrow (n^2 - 4)(n^2 - 1) \geq 0 \quad \text{clearly holds for all } n \geq 2$$

**For polynomials, we can drop everything except  $n^k$ , where  $k$  is the largest exponent**

# Big-O Notation and Logarithms

Recall  $\log_b n = \log_x n / \log_x b$

- $\log_b n = O(\log_x n)$  for every  $x > 0$
- With big-O notation, the base of the logarithm is unimportant!

$$5n^5 \log_3 n - 3n^2 \log_2 \log_2 n = O(n^5 \log n)$$

# Mathematics with Big-O Notation

If  $f(n) = O(n^3) + O(n)$ , then  $f(n) = O(n^3)$

Can simply select the largest term

What does  $f(n) = 3^{O(n)}$  mean?

$3^{O(n)} \geq 3^{cn}$  for some constant  $c$

How about  $O(1)$ ?

$O(1) \geq c$  for some constant  $c$

**Constant time**

# Exponentials

What about  $f(n) = 2^{O(\log n)}$ ?

$$n = 2^{\log_2 n} \text{ [identity]}$$

$$n^c = 2^{c \log_2 n} \text{ [identity]}$$

$$n^c = 2^{O(\log n)} \text{ [upper bound of } n^c \text{ for some } c]$$

$$2^{O(\log n)} = n^{O(1)} \text{ [equivalent upper bound]}$$

An algorithm takes **polynomial time** if its complexity is  $O(n^k)$  for some  $k > 0$

An algorithm takes **exponential time** if its complexity is  $O(a^{n^i})$ , where  $a \geq 2$ ,  $i > 0$

# Small-o Notation

**Definition:** Let  $f$  and  $g$  be two functions from  $\mathbb{N}$  to  $\mathbb{R}^+$ .

Then  $f(n) = o(g(n))$

$$\lim_{n \rightarrow \infty} (f(n)/g(n)) = 0$$

That is, for *any* positive real number  $c$ , a number  $n_0$  exists such that for every  $n \geq n_0$ ,  $f(n) < c \times g(n)$

# Big-O *versus* Small-o

If  $f(n) = o(g(n))$  then  $f(n) = O(g(n))$ , but the reverse is not always true

Big-O is like “less than or equal” while small-o is like “strictly less than”

- Example

- $f(n) = O(f(n))$  for every function  $f$
- $f(n) \neq o(f(n))$  for every function  $f$

# Some Identities

$n^i = o(n^k)$  for every  $i < k$

$\log n = o(n)$

$\log \log n = o(\log n)$

# $n$ , $\log n$ , $\log(\log n)$ , and $n \log n$

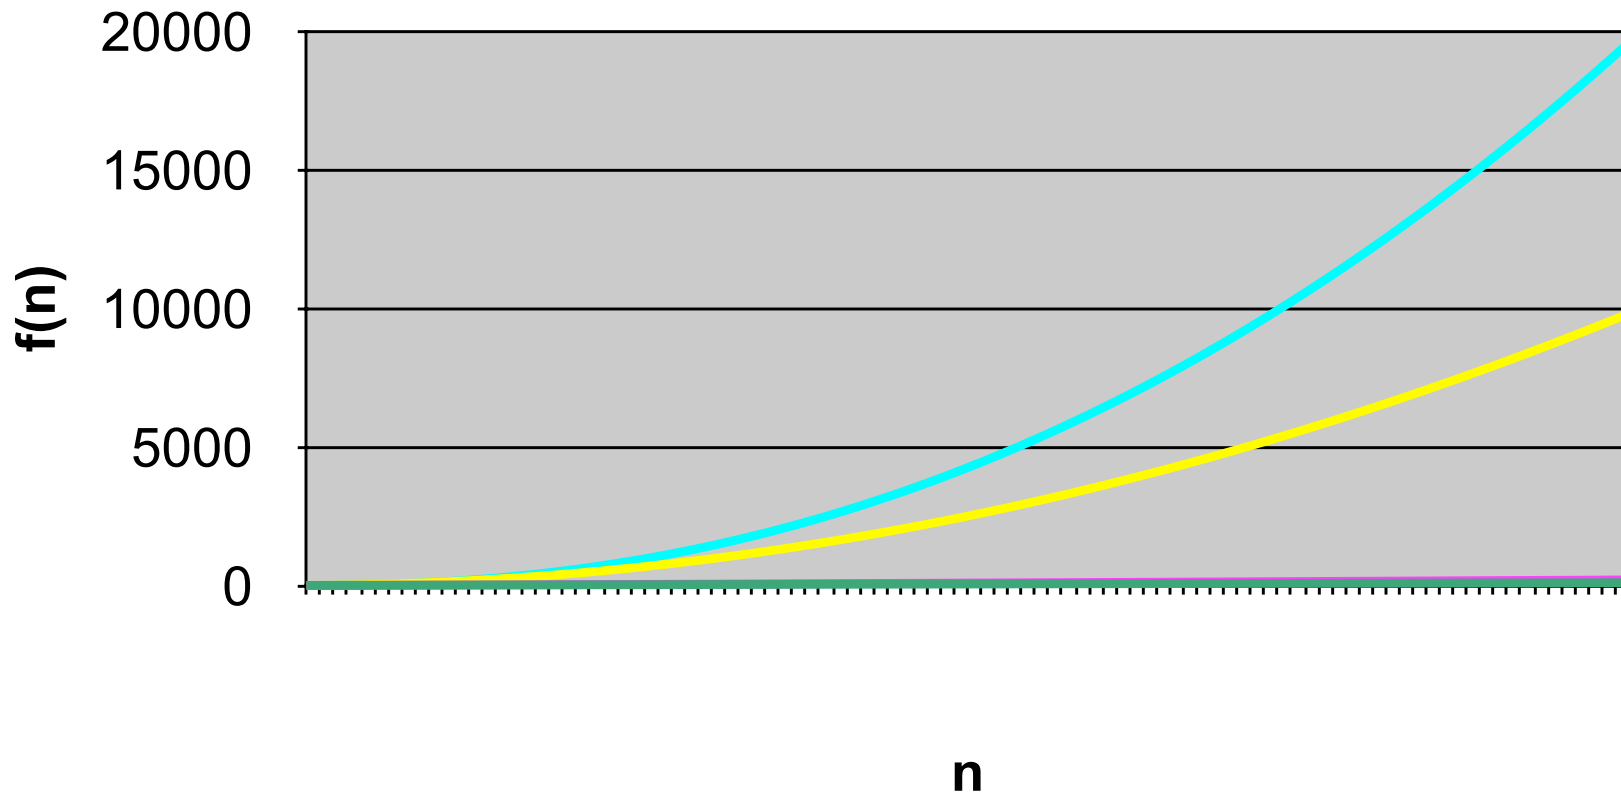

# log n and log log n

# n, n log n, n<sup>2</sup>, n<sup>2</sup> log n

# Small-o vs. Big-O

**Small-o is strictly less than**

**Big-O is less than or equal to**

**For any function  $f$ , is  $f(n) = o(f(n))$ ?**

- **No ... never!**

**For any function  $f$ , is  $f(n) = O(f(n))$ ?**

- **Yes ... always!**

# Analyzing Algorithms

We examine an algorithm to determine how long it will take to halt on an input of length  $n$

- The amount of time to complete is called the algorithm's **complexity class**

**Definition:** Let  $t:\mathbb{N}\rightarrow\mathbb{N}$  be a function.

The time complexity class,  $\text{TIME}(t(n))$ , is

$\text{TIME}(t(n)) = \{ L \mid L \text{ is a language decided by an } O(t(n))\text{-time algorithm} \}$

# Example

Earlier, we saw that insertion sort takes  $1.5 n^2 + 5.5 n - 6$  time

Insertion sort is in the time complexity class  $O(n^2)$

Insertion sort is also in the time complexity class  $O(n^k)$  for any  $k > 2$

# Importance of Model

The complexity of algorithms is a function of the **length of the input**

This length may vary depending on assumptions about our data and other model assumptions

# Another Example

Finding **minimum element** in a set

Amount of time depends on the **structure** of the input

If set is a sorted array?

- $O(1)$

If set is an unsorted array?

- $O(n)$

If set is a balanced sorted tree?

# Sorted Tree

# Sorted Tree Examined

**Finding minimum involves selecting left child until you reach a leaf**

- **Number of steps = depth of tree**

**Since the tree is balanced, the depth of the tree is  $O(\log n)$**

**What if the tree was not balanced?**

# Size of Input: Important Consideration

The running time is measured in terms of the size of the input

- If we increase the input size can that make the problem *seem* more efficient
- For example, represent integers in unary instead of binary

We consider only reasonable encodings

- The space used to encode the integer value  $v$  must be  $O(\log v)$

# Unary vs. Binary Encoding

**In unary encoding, the value 13 is encoded  
1111111111111**

- Length of encoding of value  $v$  is  $v$

**In binary encoding, the value 13 is encoded  
1101**

- Length of encoding of value  $v$  is  $\lfloor \log_2 v \rfloor + 1$

# Why does encoding matter?

Assume an algorithm takes as its input an integer of value  $v$

What is the time complexity of an algorithm if it takes integer input with value  $v$  and executes for  $v$  steps?

- Recall time complexity is a function of the **length** of the input

If encoding is in unary, the complexity is  $O(n)$

If encoding is binary, the complexity is  $O(2^n)$

# Example

**An important problem in cryptography is prime factorization**

- **Most encryptions rely on the fact that prime factorization takes a long time (exponential in the length of the input)**

**Clearly, we can find the prime factorization of  $v$  by checking whether each integer smaller than  $v$  divides it**

# Prime Factorization

**PRIME\_FACTOR(v)**

**w = v**

**factors =  $\emptyset$**     factors is a multiset & will contain prime factors

**for i = 2 to v**

**do while i divides w**

**w = w / i**

**factors = factors  $\cup$  {i}**

**enddo**

**if w = 1 break**

**next**

Worst case execution time is v  
(occurs when v is prime)

# Complexity of Prime Factorization

The algorithm has complexity  $O(v)$

- $v$  is the **value** of the input

A trickster could claim they have a linear algorithm simply by changing the encoding of the input

- If the input is unary, then the factorization is linear in the length of the input
  - **But this is cheating!**

Enforcing reasonable encodings keeps this trick from occurring
